

# Let the MC68701 Program Itself

Arnold J. Morales and David Ruhberg  
Motorola Inc.  
3501 Ed Bluestein Blvd.  
Austin, TX 78721

The Motorola MC68701 is an enhanced version of the MC6801 microprocessor. One of its chief features is the ability to program itself. The processing unit controls all movement of data into an on-chip EPROM (erasable programmable read-only memory). It controls programming power ( $V_{pp}$ ) to the EPROM during programming, requiring only a few external devices to accomplish this.

On-chip resources of the MC68701 include a 2K-byte EPROM, a three-function timer, a serial-communication interface, up to 29 parallel I/O (input/output) lines, 128 bytes of RAM (random-access read/write memory), and an oscillator. These items provide a great deal of power and flexibility in a small package that's easy to use and design with.

In this article, we will explore how the MC68701 programs itself. We'll also discuss a fully tested MC68701 programmer, including software and a hardware design.

### On-Chip EPROM

A dual-purpose MC68701 pin,  $\overline{\text{RESET}}/V_{pp}$ , is used both to reset the processor and to power the EPROM. This pin is normally +5 volts (V) during nonprogramming operation. It must be raised to  $V_{pp}$  ( $21\text{ V} \pm 1\text{ V}$ ) during programming of the EPROM. However, the processor will operate normally with  $V_{pp}$  applied at all times.

The MC68701 EPROM is controlled by two bits in the RAM/EPROM control register (see figure 1). Bit 0 of the register is called the programming latch control (PLC) and is used to control an address latch used during programming of the EPROM. Bit 1 of the register is called

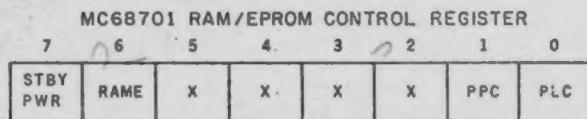

Figure 1: The RAM/EPROM control register. See the text for details of its operation.

the programming power control (PPC) and is used to control  $V_{pp}$  to the EPROM during programming.

When PLC is set, the latch is transparent. When PLC is clear, the address latch is enabled and latches each EPROM address asserted by the processor. PLC should be set during normal nonprogramming processor operation; it should be cleared only to program the EPROM. This bit is set at  $\overline{\text{RESET}}$  and can be cleared only in Mode 0 (more about modes later).

When PPC is set,  $V_{pp}$  is not applied to the EPROM; when PPC is clear,  $V_{pp}$  is applied to the EPROM. PPC should be set during normal nonprogramming operation; it should be cleared only to program the EPROM. This bit is set at  $\overline{\text{RESET}}$  and whenever the PLC bit is set, and can be cleared only in Mode 0 with the PLC bit clear.

The MC68701 is programmed in Mode 0 only. In this mode, all the interrupt vectors and reset vectors are in the locations BFF0 to BFFF hexadecimal, and the on-chip EPROM is at locations F800 to FFFF hexadecimal. The

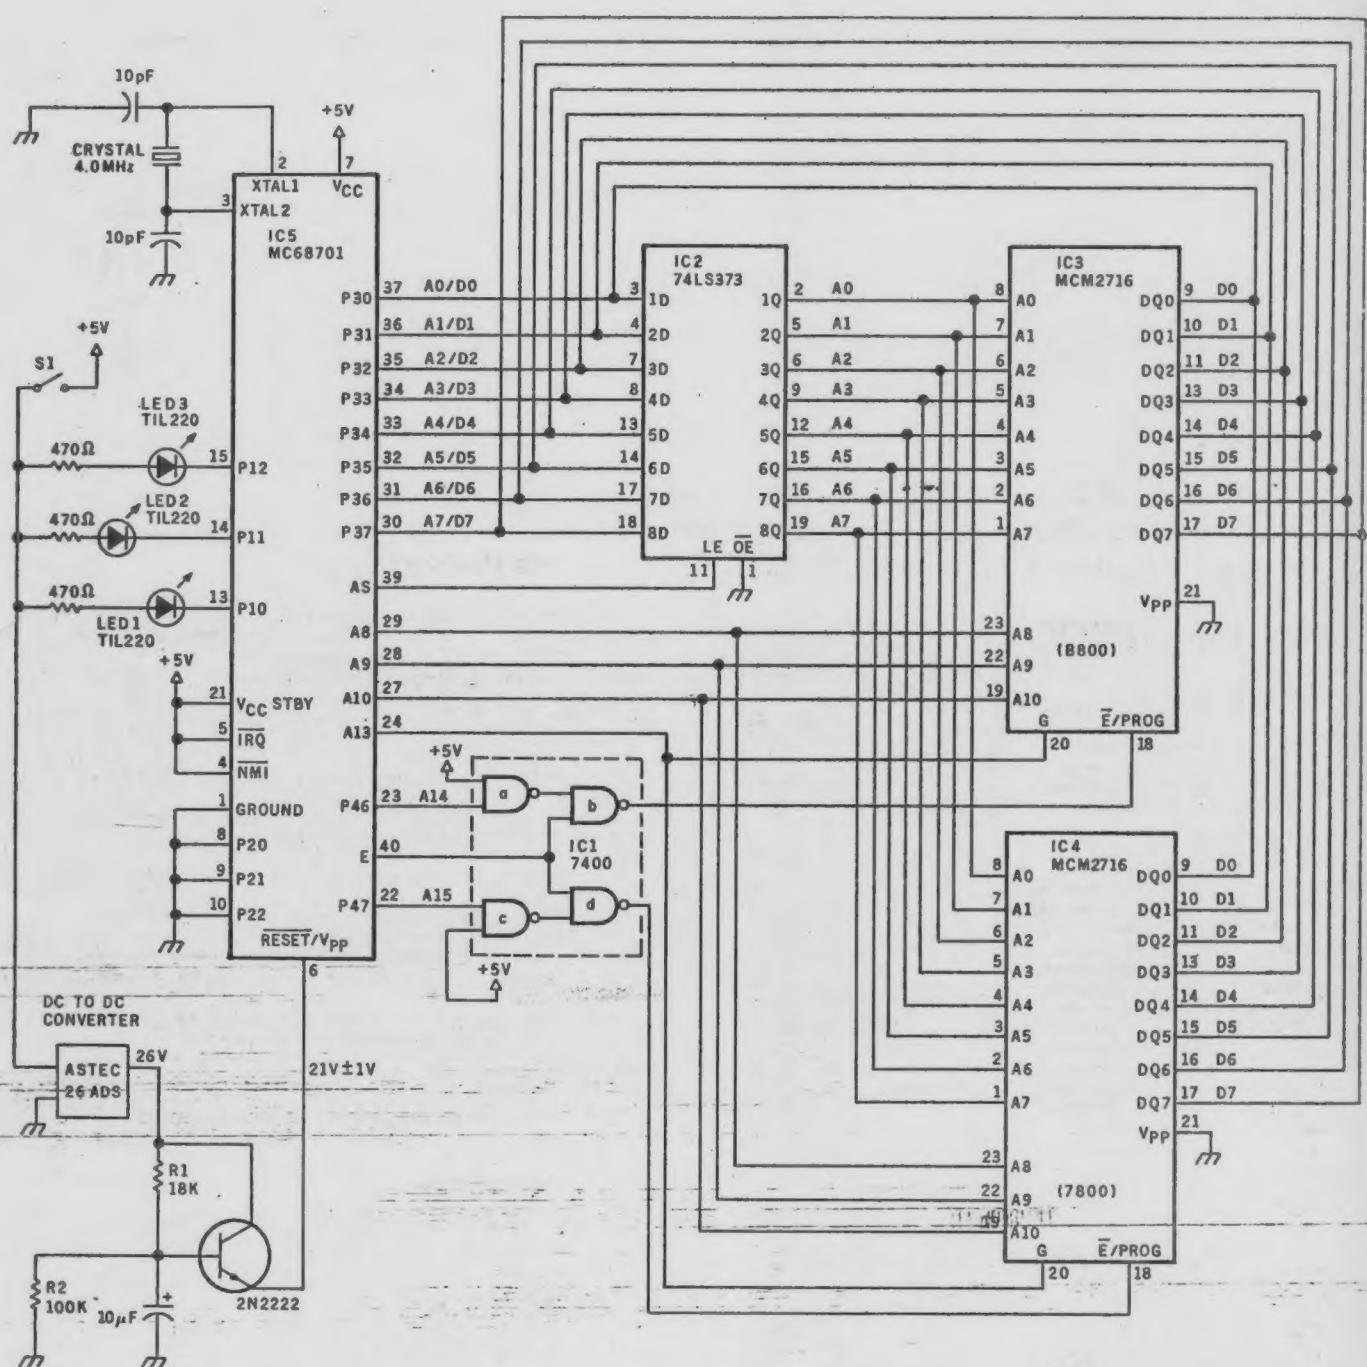

Figure 2: Programmer for the MC68701. The simplicity of this inexpensive circuit means easy construction and use. In combination with the software provided in listing 1, LEDs in the programmer can indicate that the EPROM is initially erased and that the newly stored data pass or fail a verification test.

reset vectors should direct the processor to what is essentially a bootstrap-loading program that will fetch data sequentially from memory or a peripheral controller and "burn" each byte into the EPROM. Once  $V_{pp}$  is applied to the RESET/V<sub>pp</sub> pin, each data byte is programmed into the onboard EPROM as follows:

1. Clear the PLC bit and set the PPC bit. This enables the EPROM address latch and inhibits  $V_{pp}$  to the EPROM.
2. Write data to the EPROM location to be programmed. Both the data and address will be captured by internal latches.

3. Clear the PPC bit for 50 milliseconds (ms). This controls programming power to the EPROM, allowing the data byte to be burned in.

These steps are repeated until all bytes have been programmed.

#### An MC68701 Programmer

Fully assembled and tested modules designed to program the MC68701 are available through Motorola distributors. Some users, however, may require custom programming boards designed to meet specific needs.

JOHN STARKWEATHER'S

# NEVADA PILOT

**\$149.95**

DISKETTE AND MANUAL

Vector and many other microcomputers. Needs 32K RAM, one disk drive and CRT or video display and keyboard.

- PILOT for Programmed, Inquiry, Learning Or Teaching.
- An excellent interactive language for education and office automation.
- Perfect companion for **BASIC**, **COBOL** and **PASCAL** to solve training and documentation problems.
- John Starkweather, Ph.D., creator of PILOT, wrote this version to meet all PILOT-73 standards and added many new features.
- New features include full screen text editor, commands to drive optional equipment such as VTR's & voice response units.
- Currently used in many college and progressive high schools.
- Use for interactive applications—data entry, programmed instruction and testing.

For all CP/M systems. Works with Apple (softcard needed), Osborne 1, TRS-80, North Star, Superbrain, Micropolis, one

**(415) 751-1522**

The programmer described in this article (see figure 2) is designed for simplicity, low cost, and ease of use. The hardware and associated software verify that an inserted MC68701 is initially fully erased, do the programming, and verify the "entered" code. The user only applies power and monitors three light-emitting diodes (LEDs) that indicate EPROM status. The programmer enters the entire 2K-byte content of EPROM IC4 into the MC68701 EPROM. The system can be modified to, for instance, provide more detailed failure information or to program only a portion of the EPROM.

## Using the Programmer

The user needs no knowledge of MC68701 operation and very little knowledge of electronics in order to use the programmer. Four steps are required:

1. Insert the EPROM containing the code to be programmed into the MC68701 into the socket at IC4.
2. Insert the MC68701 into the socket.
3. Apply power.
4. Monitor LEDs.

Within a few seconds after power is applied, LED 1 should light, indicating that the MC68701 EPROM is fully erased. Approximately 105 seconds after power is applied, LED 2 should light, indicating that the EPROM has been programmed and its contents verified. At this time, power can be removed from the system, and another MC68701 can be programmed.

LED 3 will light to indicate either a not fully erased MC68701 EPROM when power is initially applied, or failure to verify after attempted programming. If LED 3 lights and LED 1 is not lit, the MC68701 was not fully erased when inserted into the board. If this occurs, no attempt is made to program the EPROM. If LED 3 lights while LED 1 is lit, the EPROM's contents did not verify after attempted programming.

The LEDs should be color-coded to give readily recognized *pass* and *fail* indication. A good color scheme is amber for LED 1 (erased), green for LED 2 (pass), and red for LED 3 (fail). Zero insertion force sockets should be used for the MC68701 and EPROM.

## Memory Map

The memory map, consisting of five special address spaces, is shown in figure 3. Four of the address spaces are fixed by the MC68701 during programming and cannot be relocated. These consist of an internal-register area (0000 to 001F hexadecimal), internal RAM (0080 to 00FF hexadecimal), external interrupt vectors (BFF0 to BFFF hexadecimal), and internal EPROM (F800 to FFFF hexadecimal).

A fifth address space is used for an MCM2716 that contains the code to be entered into the MC68701 on-chip EPROM. This MCM2716 has been arbitrarily placed at locations 7800 to 7FFF hexadecimal and can be relocated for custom programmer design.

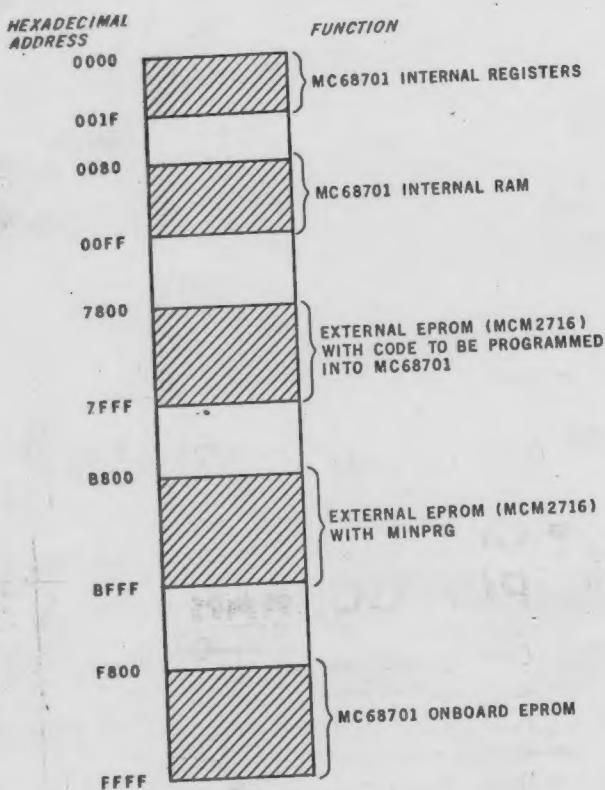

Figure 3: Memory map of the MC68701 address space.

For ease of decoding, an MCM2716 containing MINPRG, the programmer bootstrap program, is based at location B800 hexadecimal. The system RESET vectors are located at the top of the EPROM and decode at locations BFFE to BFFF hexadecimal.

### Circuit Description

The MC68701 programmer consists of two MCM2716 EPROMs, a 74LS373 transparent latch, a 74LS00 NAND gate package, an MC68701 socket, and associated "glue," as shown in figure 2.

A 4-megahertz (MHz) crystal is used to yield 1-MHz operation. This clock frequency can be increased to accommodate higher-speed MC68701s, but changes in the operating frequency require changes in the MINPRG bootstrap software to ensure 50 ms programming time for each byte entered into the EPROM, or to minimize programming time.

This delay is governed by the value of WAIT in MINPRG and is indirectly related to the clock frequency. An increase in the clock frequency requires a proportional increase in the value of WAIT; a decrease of the clock frequency allows a proportional decrease in the value of WAIT.

The MC68701 can also be driven by an external transistor-transistor logic (TTL) clock at pin 3, with pin 2 grounded. If this clock option is used, the capacitors tied to pins 2 and 3, used to ensure stable crystal operation, are not required.

Pins 8, 9, and 10 are tied to ground to place the MC68701 into Mode 0 (programming mode) at RESET. IRQ (interrupt request) and NMI (nonmaskable interrupt) are tied high to eliminate external interrupts.

Three LEDs are tied to I/O pins 13, 14, and 15. They are used to indicate the state of the MC68701 EPROM during programming operations. High-current drivers force the pins low to light the LEDs.

The  $\overline{\text{RESET}}/V_{pp}$  pin is driven by a transistor to assure adequate power to the pin during programming. The base of this transistor is controlled by an RC (resistor-capacitor) network that provides adequate delay between

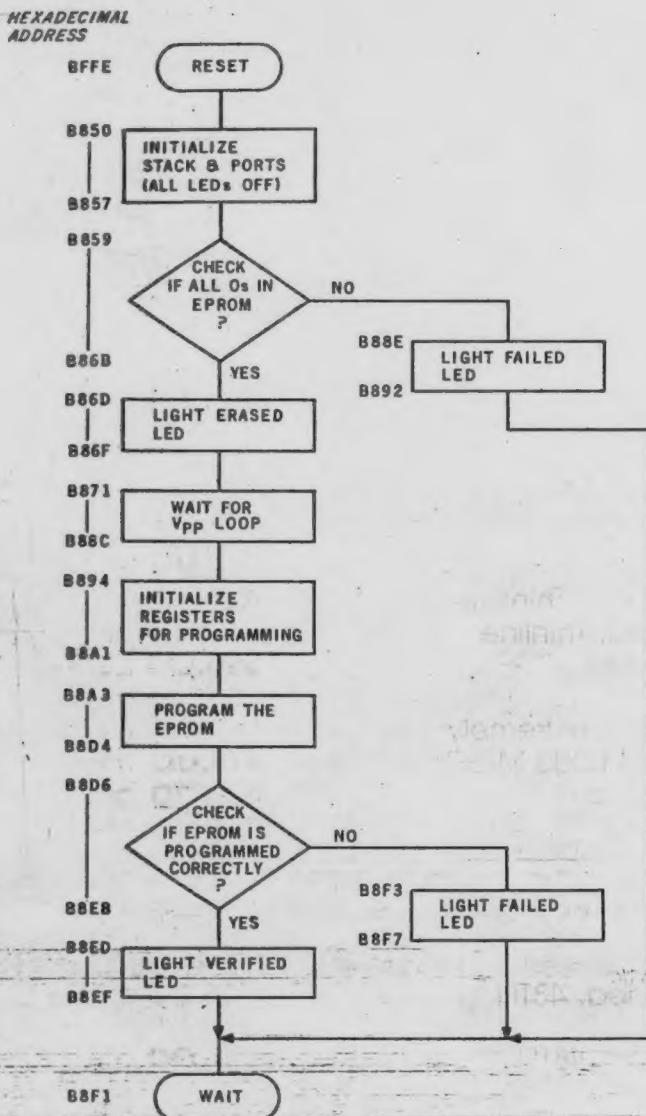

Figure 4: Flowchart of the programmer software called MINPRG. The program is shown in listing 1.

Text continued from page 386:

the application of  $V_{cc}$  and  $\overline{RESET}$ . During programming,  $21\text{ V} \pm 1\text{ V}$  ( $V_{pp}$ ) must be applied to the  $\overline{RESET}/V_{pp}$  pin. A 5- to 26-V voltage converter is used to eliminate the need for two power supplies.  $R1$  and  $R2$  form a voltage divider that provides a proper voltage level to the  $\overline{RESET}/V_{pp}$  pin.  $R2$  also serves to discharge  $C1$  during power-down.

A 74LS373 transparent latch is used to demultiplex port 3, which is used both as a lower address port (signals  $A_0$  through  $A_7$ ) and as a data port. An address strobe (AS) from the MC68701 is tied to latch enable (LE) of the 74LS373 to latch the lower-order address at the proper time each bus cycle. Once the lower address is latched, the port is used for data transfer.

Four NAND gates are used for address decoding of the two external EPROMs. Each EPROM is selected with high  $A_{13}$  to ensure deselection during access of MC68701 internal RAM and internal registers. EPROM IC3 drivers are enabled with low  $A_{14}$  and high  $E$ ; EPROM IC4 drivers

are enabled with low  $A_{15}$  and high  $E$ . Controlling with  $E$  ensures that drivers are in the high-impedance state during  $E$  low, eliminating driver contention on the multiplexed lower-address/data bus. Controlling the drivers with low  $A_{14}/A_{15}$  assures separation between the off-chip and on-chip EPROM address spaces. EPROM IC3, containing MINPRG, is selected at locations B800 to BFFF hexadecimal; EPROM IC4, containing the program to be entered into the MC68701 EPROM, is selected at locations 7800 to 7FFF hexadecimal. Incomplete address decoding is used for IC3 and IC4 to minimize the number of devices used in the system, allowing their selection in several address spaces. Care must be taken when writing software for the system to ensure that only one device is accessed at any time.

Note that only Motorola MCM2716 EPROMs allow an optional active high chip select (pin 20) by tying  $V_{pp}$  (pin 21) low during reads. If non-Motorola 2716 EPROMs are used,  $V_{pp}$  must be tied high and  $A_{13}$  must be inverted to the active low chip selects.

### Program Description

The programmer uses a bootstrap program, MINPRG, to control programming of the MC68701 EPROM. The program performs the following functions:

1. Initialize the MC68701.
2. Check that the EPROM is erased.
3. Program the EPROM.
4. Verify the program.
5. Stop.

MINPRG also controls three LEDs that indicate MC68701 EPROM status during programmer operation. A detailed flowchart of MINPRG is shown in figure 4; a complete listing is shown in listing 1 on page 388.

### Program Modifications and Considerations

Additions and modifications to this code can be made easily by inserting routines between the basic blocks on the flowchart. For convenience, the start and stop addresses of each block are located directly to the left of each block.

Parameters IMBEG, IMEND, PNTR, and WAIT, stored in RAM locations 80 to 87 hexadecimal, determine the size of the data block to be programmed into the MC68701, the first MC68701 EPROM location to be programmed, and the time period each byte will be burned into the EPROM. These parameters can be changed to allow programming of selected EPROM locations and to allow changes in operating frequency. These parameters, once selected, should remain constant throughout the entire program.

A modification to MINPRG that should be considered is verification of the EPROM if the EPROM is not initially erased, rather than to simply light LED 1 and wait. This change would allow verification of MC68701 EPROMs that have already been programmed and used. ■

## Advance Information

### MC68701 MICROCOMPUTER UNIT (MCU)

The MC68701 is an 8-bit single chip microcomputer unit (MCU) which significantly enhances the capabilities of the M6800 family of parts. It can be used in production systems to allow for easy firmware changes with minimum delay or it can be used to emulate the MC6801/03 for software development. It includes an upgraded M6800 microprocessor unit (MPU) while retaining upward source and object code compatibility. Execution times of key instructions have been improved and several new instructions have been added including an unsigned multiply. The MCU can function as a monolithic microcomputer or can be expanded to a 64K byte address space. It is TTL compatible and requires one +5 volt power supply for nonprogramming operation. An additional VPP power supply is needed for EPROM programming. On-chip resources include 2048 bytes of EPROM, 128 bytes of RAM, Serial Communications Interface (SCI), parallel I/O, and a three function Programmable Timer. A summary of MCU features includes:

- Enhanced MC6800 Instruction Set
- 8x8 Multiply Instruction
- Serial Communications Interface (SCI)
- Upward Source and Object Code Compatible with MC6800
- 16-Bit Three-Function Programmable Timer
- Single-Chip or Expandable to 64K-Byte Address Space
- Bus Compatible with M6800 Family
- 2048 Bytes of UV Erasable, User Programmable ROM
- 128 Bytes of RAM (64 Bytes Retainable on Powerdown)
- 29 Parallel I/O and Two Handshake Control Lines
- Internal Clock Generator with Divide-by-Four Output

## MAXIMUM RATINGS

Rating	Symbol	Value	Unit
Supply Voltage	V <sub>CC</sub>	-0.3 to +7.0	Vdc
Input Voltage	V <sub>in</sub>	-0.3 to +7.0	Vdc
Operating Temperature Range	T <sub>A</sub>	0 to 50	°C
Storage Temperature Range	T <sub>stg</sub>	0 to +85	°C

This device contains circuitry to protect the inputs against damage due to high static voltages or electric fields; however, it is advised that normal precautions be taken to avoid application of any voltage higher than maximum rated voltages to this high-impedance circuit. For proper operation it is recommended that V<sub>in</sub> and V<sub>out</sub> be constrained to the range V<sub>SS</sub> ≤ (V<sub>in</sub> or V<sub>out</sub>) ≤ V<sub>CC</sub>.

## INTRODUCTION

The MC68701 is an 8-bit monolithic microcomputer which can be configured to function in a wide variety of applications. The facility which provides this extraordinary flexibility is its ability to be hardware programmed into eight different operating modes. The operating mode controls the configuration of 18 of the MCU's 40 pins, available on-chip resources, memory map, location (internal or external) of interrupt vectors, and type of external bus. The configuration of the remaining 22 pins is not dependent on the operating mode.

Twenty-nine pins are organized as three 8-bit ports and one 5-bit port. Each port consists of at least a Data Register and a write-only Data Direction Register. The Data Direction Register is used to define whether corresponding bits in the Data Register are configured as an input (clear) or output (set).

The term "port," by itself, refers to all of its associated hardware. When the port is used as a "data port" or "I/O port," it is controlled by its Data Direction Register and the programmer has direct access to its pins using the port's Data Register. Port pins are labeled as  $P_{ij}$  where  $i$  identifies one of four ports and  $j$  indicates the particular bit.

The Microprocessor Unit (MPU) is an enhanced MC6800 MPU with additional capabilities and greater throughput. It is upward source and object code compatible with the MC6800. The programming model is depicted in Figure 11

where Accumulator D is a concatenation of Accumulators A and B. A list of new operations added to the MC6800 instruction set are shown in Table 1.

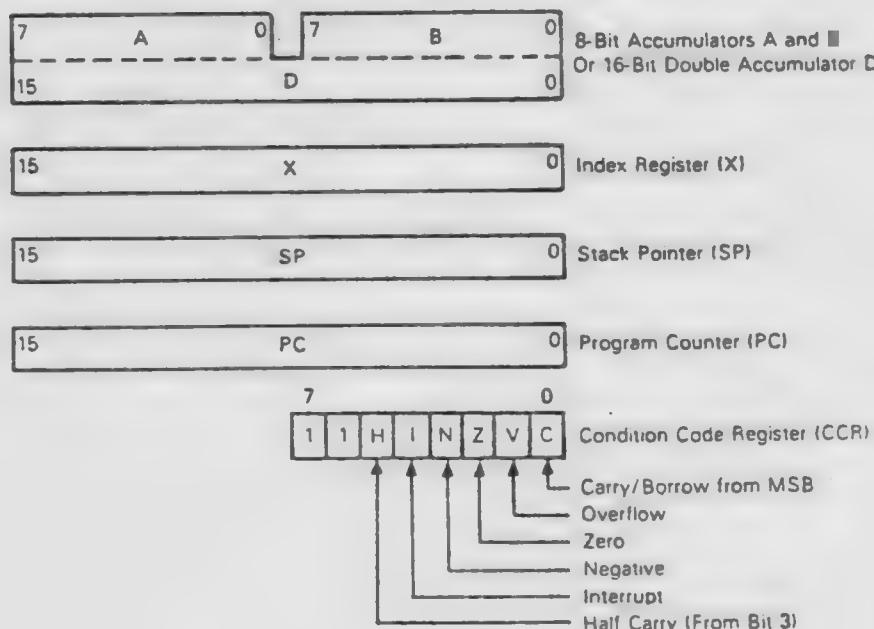

The basic difference between the MC6801 and the MC68701 is that the MC6801 has an onboard ROM while the MC68701 has an onboard EPROM. The MC68701 is pin and code compatible with the MC6801 and can be used to emulate the MC6801, allowing easy software development using the onboard EPROM. Software developed using the MC68701 can then be masked into the MC6801 ROM.

In order to support the onboard EPROM, the MC68701 differs from the MC6801 as follows:

- (1) Mode 0 in the MC6801 is a test mode only, while in the MC68701 Mode 0 is also used to program the onboard EPROM and has interrupt vectors at \$BFF0-\$BFFF rather than \$FFF0-\$FFFF.
- (2) The MC68701 RAM/EPROM Control Register has two bits used to control the EPROM in Mode 0 that are not defined in the MC6801 RAM Control Register.
- (3) The RESET/V<sub>pp</sub> pin in the MC68701 is dual purpose, used to supply EPROM power as well as to reset the device; while in the MC6801 the pin is called RESET and is used only to reset the device.

In addition, MC6801 modes 1R and 6R, available as a mask option, are not available in the MC68701.

FIGURE 11 — MC68701/6801/6803 PROGRAMMING MODEL

**MOTOROLA Semiconductor Products Inc.**

TABLE 1 — NEW INSTRUCTIONS

Instruction	Description
ABX	Unsigned addition of Accumulator B to Index Register
ADDD	Adds (without carry) the double accumulator to memory and leaves the sum in the double accumulator
ASLD or LSLD	Shifts the double accumulator left (towards MSB) one bit; the LSB is cleared and the MSB is shifted into the C-bit
BHS	Branch if Higher or Same, unsigned conditional branch (same as BCC)
BLO	Branch if Lower, Unsigned conditional branch (same as BCS)
BRN	Branch Never
JSR	Additional addressing mode, direct
LDD	Loads double accumulator from memory
LSL	Shifts memory or accumulator left (towards MSB) one bit; the LSB is cleared and the MSB is shifted into the C-bit (same as ASL)
LSRD	Shifts the double accumulator right (towards LSB) one bit; the MSB is cleared and the LSB is shifted into the C-bit
MUL	Unsigned multiply; multiplies the two accumulators and leaves the product in the double accumulator
PSHX	Pushes the Index Register to stack
PULX	Pulls the Index Register from stack
STD	Stores the double accumulator to memory
SUBD	Subtracts memory from the double accumulator and leaves the difference in the double accumulator
CPX	Internal processing modified to permit its use with any conditional branch instruction

## OPERATING MODES

The MCU provides eight different operating modes which are selectable by hardware programming and referred to as Mode 0 through Mode 7. The operating mode controls the memory map, configuration of Port 3, Port 4, SC1, SC2, and the physical location of interrupt vectors.

### FUNDAMENTAL MODES

The MCU's eight modes can be grouped into three fundamental modes which refer to the type of bus it supports: Single Chip, Expanded Non-Multiplexed, and Expanded Multiplexed. Modes 4 and 7 are Single Chip Modes. Mode 5 is the Expanded Non-Multiplexed Mode, and the remaining modes are Expanded Multiplexed Modes. Table 2 summarizes the characteristics of the operating modes.

#### Single Chip Modes (4, 7)

In Single-Chip Mode, the MCU's four ports are configured as parallel input/output data ports, as shown in Figure 12. The MCU functions as a monolithic microcomputer in these two modes without external address or data buses. A maximum of 29 I/O lines and two Port 3 control lines are provided. In addition to other peripherals, another MCU can be interfaced to Port 3 in a loosely coupled dual processor configuration, as shown in Figure 13.

In Single-Chip Test Mode (4), the RAM responds to \$XX20 through \$XXFF and the EPROM is removed from the internal address map. A test program must first be loaded into the RAM using modes 0, 1, 2, or 6. If the MCU is Reset and then programmed into Mode 4, execution will begin at \$XXFE:XXFF. Mode 5 can be irreversibly entered from Mode 4 without going through Reset by setting bit 5 of Port 2's Data Register. This mode is used primarily to test Ports 3 and 4 in the Single-Chip and Non-Multiplexed Modes.

TABLE 2 — SUMMARY OF MC68701 OPERATING MODES

Common to all Modes:	Reserved Register Area Port 1 Port 2 Programmable Timer Serial Communications Interface
Single Chip Mode 7	128 bytes of RAM; 2048 bytes of EPROM Port 3 is a parallel I/O port with two control lines Port 4 is a parallel I/O port SC1 is Input Strobe 3 (IS3) SC2 is Output Strobe 3 (OS3)
Expanded Non-Multiplexed Mode 5	128 bytes of RAM; 2048 bytes of EPROM 256 bytes of external memory space Port 3 is an 8-bit data bus Port 4 is an input port/address bus SC1 is Input/Output Select (IOS) SC2 is Read/Write (R/W)
Expanded Multiplexed Modes 1, 2, 3, 6	Four memory space options (64K address space): (1) No internal RAM or EPROM (Mode 3) (2) Internal RAM, no EPROM (Mode 2) (3) Internal RAM and EPROM (Mode 1) (4) Internal RAM, EPROM with partial address bus (Mode 6) Port 3 is a multiplexed address/data bus Port 4 is an address bus (inputs/address in Mode 6) SC1 is Address Strobe (AS1) SC2 is Read/Write (R/W)
Test Mode 4	(1) May be changed to Mode 5 without going through Reset (2) May be used to test Ports 3 and 4 as I/O ports
Expanded Multiplexed Mode 0	(1) Internal RAM and EPROM (2) External interrupt vectors located at \$BFF0-\$BFFF (3) Used to program EPROM

## MC68000 MODES

### Expanded Non-Multiplexed Mode (5)

A modest amount of external memory space is provided in the Expanded Non-Multiplexed Mode while retaining significant on-chip resources. Port 3 functions as an 8-bit bidirectional data bus and Port 4 is configured as an input data port. Any combination of the eight least-significant address lines may be obtained by writing to Port 4's Data Direction Register. Stated alternatively, any combination of A0 to A7 may be provided while retaining the remainder as input data lines. Internal pullup resistors are intended to pull Port 4's lines high until it is configured.

Figure 14 illustrates a typical system configuration in the Expanded Non-Multiplexed Mode. The MCU interfaces directly with M6800 family parts and can access 256 bytes of external address space at \$100 through \$1FF.  $\overline{IOS}$  provides an address decode of external memory (\$100-\$1FF) and can be used similarly to an address or chip select line.

### Expanded-Multiplexed Modes (0, 1, 2, 3, 6)

In the Expanded-Multiplexed Modes, the MCU has the ability to access a 64K byte memory space. Port 3 functions as a time multiplexed address/data bus with address valid on the negative edge of Address Strobe (AS) and the data bus valid while E is high. In Modes 0 to 3, Port 4 provides address lines A8 to A15. In Mode 6, however, Port 4 is configured during RESET as data port inputs and the Data Direction Register can be changed to provide any combination of address lines, A8 to A15. Stated alternatively, any subset of A8 to A15 can be provided while retaining the remainder as input data lines. Internal pullup resistors are intended to pull Port 4's lines high until software configures the port.

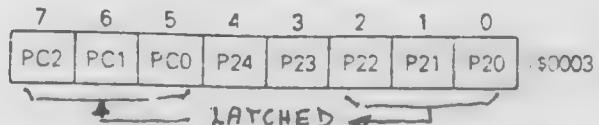

Figure 15 depicts a typical configuration for the Expanded-Multiplexed Modes. Address Strobe can be used to control a transparent D-type latch to capture addresses A0 to A7, as shown in Figure 16. This allows Port 3 to function as a Data Bus when E is high.

In Mode 0, the internal and external data buses are connected; there must therefore be no memory map overlap in order to avoid potential bus conflicts. Mode 0 is used to program the on board EPROM. All interrupt vectors are external in this mode and are located at \$BFF0-\$BFFF.

### PROGRAMMING THE MODE

The operating mode is programmed by the levels asserted on P22, P21, and P20 which are latched into PC2, PC1, and PC0 of the program control register on the positive edge of RESET. The operating mode may be read from Port 2's Data Register as shown below, and programming levels and timing must be met as shown in Figure 17. A brief outline of the operating modes is shown in Table 3.

### PART 2 DATA REGISTER

Circuitry to provide the programming levels is dependent primarily on the normal system usage of the three pins. If configured as outputs, the circuit shown in Figure 18 may be used; otherwise, three-state buffers can be used to provide isolation while programming the mode.

### MEMORY MAPS

The MCU can provide up to 64K byte address space depending on the operating mode. A memory map for each operating mode is shown in Figure 19. The first 32 locations of each map are reserved for the MCU's internal register area, as shown in Table 4, with exceptions as indicated.

TABLE 3 — MODE SELECTION SUMMARY

RESET Rise Time $< 1 \mu s$		—	—	—	

FIGURE 18 — TYPICAL MODE PROGRAMMING CIRCUIT

## Notes:

1. Mode 0 as shown.
2.  $R1 = 10 \text{ kohms (typical)}$ .
3. The RESET time constant is equal to  $RC$  where  $R$  is the equivalent parallel resistance of  $R2$  and the number of resistors ( $R1$ ) placed in the circuit by closed mode control switches.
4.  $D = 1N914, 1N4001$  (typical).
5. If  $V = V_{CC}$ , then  $R2 = 50 \text{ ohms (typical)}$  to meet  $V_{IH}$  for the RESET/VPP pin.  $V = V_{CC}$  is also compatible with MC6801. The RESET time constant in this case is approximately  $R2 \cdot C$ .
6. Switch S1 allows selection of normal (RESET) or programming (VPP) as the input to the RESET/VPP pin. During switching, the input level is held at a value determined by a diode (D), resistor (R2) and input voltage (V).
7. While S1 is in the "Program" position, RESET should not be asserted.
8. From powerup, RESET must be held low for at least  $1\mu\text{sec}$ . The capacitor, C, is shown for conceptual purposes only and is on the order of  $1000 \mu\text{F}$  for the circuit shown. Typically, a driver with an RC input will be used to drive RESET, eliminating the need for the larger capacitor.

## MC68701 INTERRUPTS

The MCU supports two types of interrupt requests: maskable and non-maskable. A Non-Maskable Interrupt (NMI) is always recognized and acted upon at the completion of the current instruction. Maskable interrupts are controlled by the Condition Code Register's I-bit and by individual enable bits. The I-bit controls all maskable interrupts. Of the maskable interrupts, there are two types: IRQ1 and IRQ2. The Programmable Timer and Serial Communications Interface use an internal IRQ2 interrupt line, as shown in Figure 1. External devices (and TS3) use IRQ1. An IRQ1 interrupt is serviced before IRQ2 if both are pending.

All IRQ2 interrupts use hardware prioritized vectors. The single SCI interrupt and three timer interrupts are serviced in a prioritized order where each is vectored to a separate location. All MCU interrupt vector locations are shown in Table 5.

TABLE 5 – MCU INTERRUPT VECTOR LOCATIONS

Mode 0		Modes 1-7		Interrupt
MSB	LSB	MSB	LSB	
BFFE	BFFF	FFFE	FFFF	RESET
BFFC	BFFD	FFFC	FFFD	NMI
BFFA	BFFB	FFFA	FFFB	Software Interrupt (SWI)
BFF8	BFF9	FFFB	FFF9	IRQ1 (or TS3)
BFF6	BFF7	FFF6	FFF7	ICF (Input Capture)
BFF4	BFF5	FFF4	FFF5	OCF (Output Compare)
BFF2	BFF3	FFF2	FFF3	TOF (Timer Overflow)
BFFC	BFF1	FFFO	FFF1	SCI (RDRE + ORFE + TDRE)

The Interrupt flowchart is depicted in Figure 20 and is common to every MCU interrupt excluding Reset. The Program Counter, Index Register, A Accumulator, B Accumulator, and Condition Code Register are pushed to the stack. The I-bit is set to inhibit maskable interrupts and a vector is fetched corresponding to the current highest priority interrupt. The vector is transferred to the Program Counter and instruction execution is resumed. Interrupt and RESET timing are illustrated in Figures 21a and 21b.

## FUNCTIONAL PIN DESCRIPTIONS

### VCC AND VSS

VCC and VSS provide power to a large portion of the MCU. The power supply should provide +5 volts ( $\pm 5\%$ ) to VCC, and VSS should be tied to ground. Total power dissipation (including VCC Standby), will not exceed PD milliwatts.

### VCC STANDBY

VCC Standby provides power to the standby portion (\$80 through \$BF) of the RAM and the STBY PWR and RAME bits of the RAM Control Register. Voltage requirements depend on whether the MCU is in a powerup or powerdown state. In the powerup state, the power supply should provide +5 volts ( $\pm 5\%$ ) and must reach VSB volts before RESET reaches 4.0 volts. During powerdown, VCC Standby must remain above VSBB (min) to sustain the standby RAM and STBY PWR bit. While in powerdown operation, the standby current will not exceed ISBB.

It is typical to power both VCC and VCC Standby from the same source during normal operation. A diode must be used between them to prevent supplying power to VCC during powerdown operation. VCC Standby should be tied to either ground or VCC in Mode 3.

### XTAL1 AND XTAL2

These two input pins interface either a crystal or TTL compatible clock to the MCU's internal clock generator. Divide-by-four circuitry is included which allows use of the inexpensive 3.58 MHz or 4.4336 MHz Color Burst TV crystals. A 25 pF capacitor is required from each crystal pin to ground to ensure reliable startup and operation. Alternatively, EXTAL2 may be driven with an external TTL compatible clock at 4f<sub>0</sub> with a duty cycle of 50% ( $\pm 10\%$ ) with XTAL1 connected to ground.

The internal oscillator is designed to interface with an AT-cut quartz crystal resonator operated in parallel resonance mode in the frequency range specified for XTAL. The crystal should be mounted as close as possible to the input pins to minimize output distortion and startup stabilization time. The MCU is compatible with most commercially available crystals, and nominal crystal parameters are shown in Figure 22.

### RESET/VPP

This input is used to reset the MCU's internal state and provide an orderly startup procedure. During powerup, RESET must be held below 0.8 volts: (1) at least 1RC after VCC reaches VSB volts in order to provide sufficient time for the clock generator to stabilize, and (2) until VCC Standby reaches VSB volts. RESET must be held low at least three E-cycles if asserted during powerup operation.

This pin is also used to supply Vpp in Mode 0 for programming the EPROM, and supplies operating power to the EPROM during powerup operation.

### E (ENABLE)

This is an output clock used primarily for bus synchronization. It is TTL compatible and is the slightly skewed divide-by-four result of the MCU input frequency. It will drive one Schottky TTL load and 90 pF, and all data given in cycles is referenced to this clock unless otherwise noted.

### NMI (NON-MASKABLE INTERRUPT)

An NMI negative edge requests an MCU interrupt sequence, but the current instruction will be completed before it responds to the request. The MCU will then begin an interrupt sequence. Finally, a vector is fetched from \$FFFC and \$FFFD (or \$BFEC and \$BFFD in Mode 0), transferred to the Program Counter and instruction execution resumes. NMI typically requires a 3.3 k $\Omega$  (nominal) resistor to VCC. There is no internal NMI pullup resistor. NMI must be held low for at least one E-cycle to be recognized under all conditions.

### IRQ1 (MASKABLE INTERRUPT REQUEST 1)

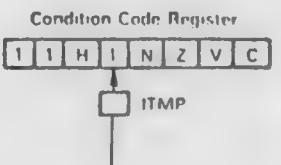

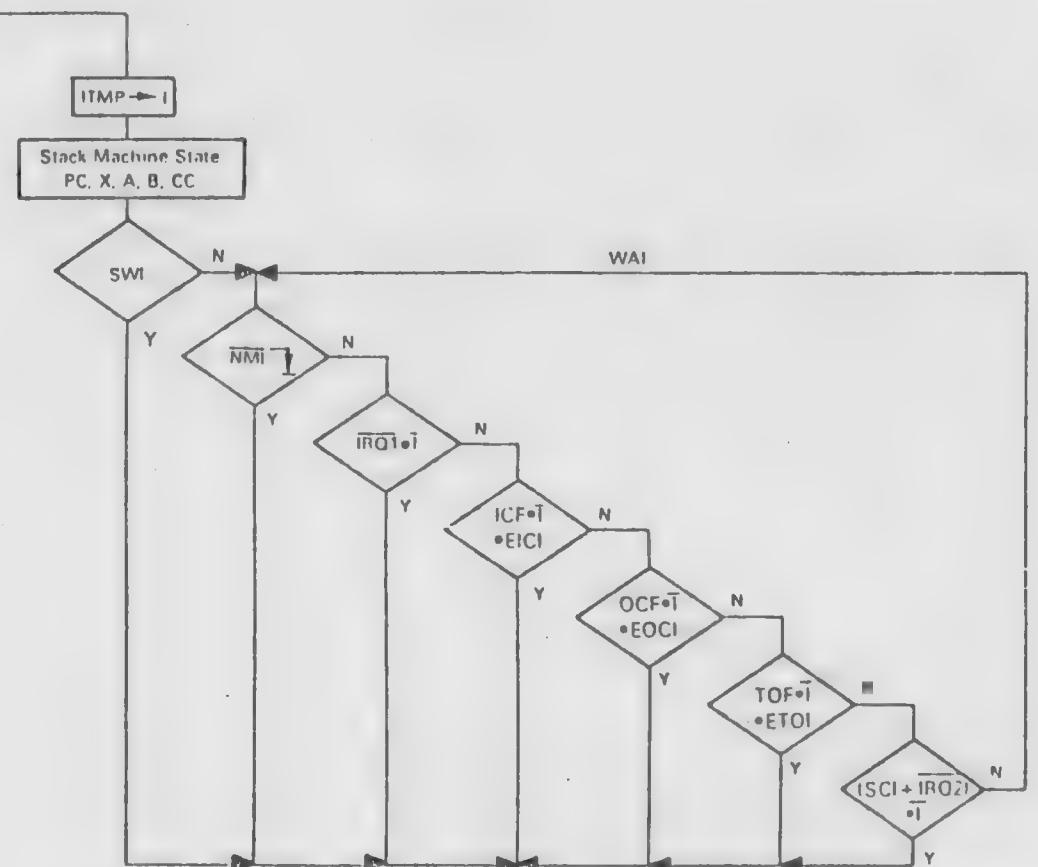

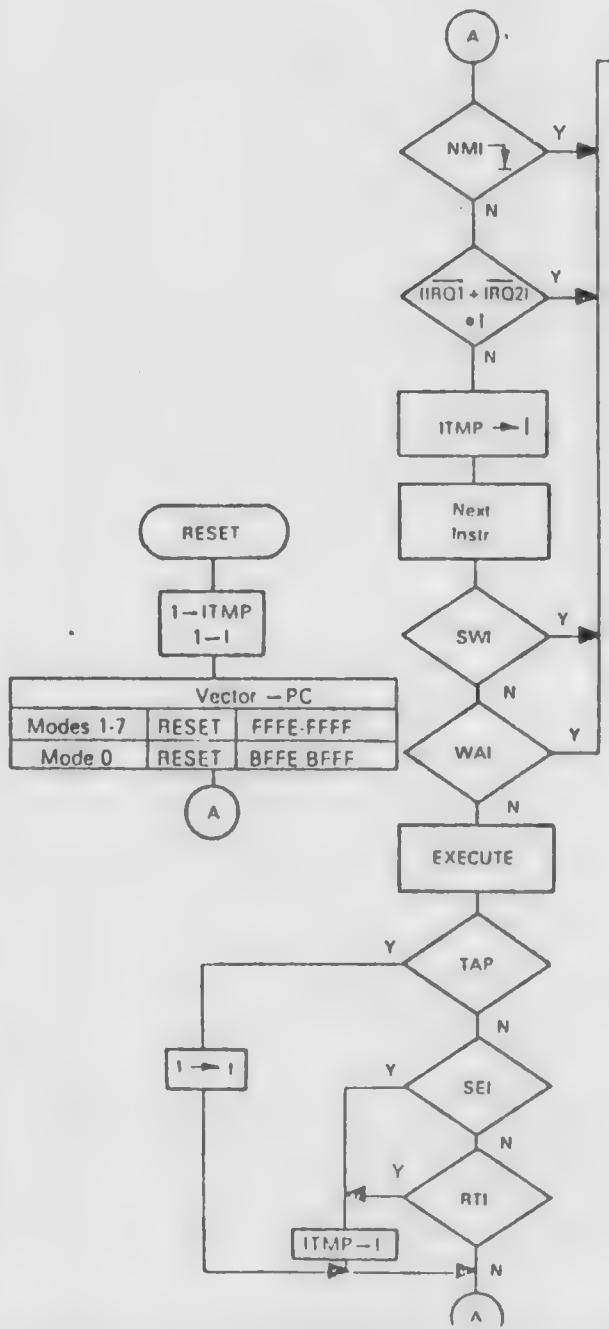

IRQ1 is a level-sensitive input which can be used to request an interrupt sequence. The MPU will complete the current instruction before it responds to the request. If the interrupt mask bit (I-bit) in the Condition Code Register is clear, the MCU will begin an interrupt sequence. Finally, a vector is

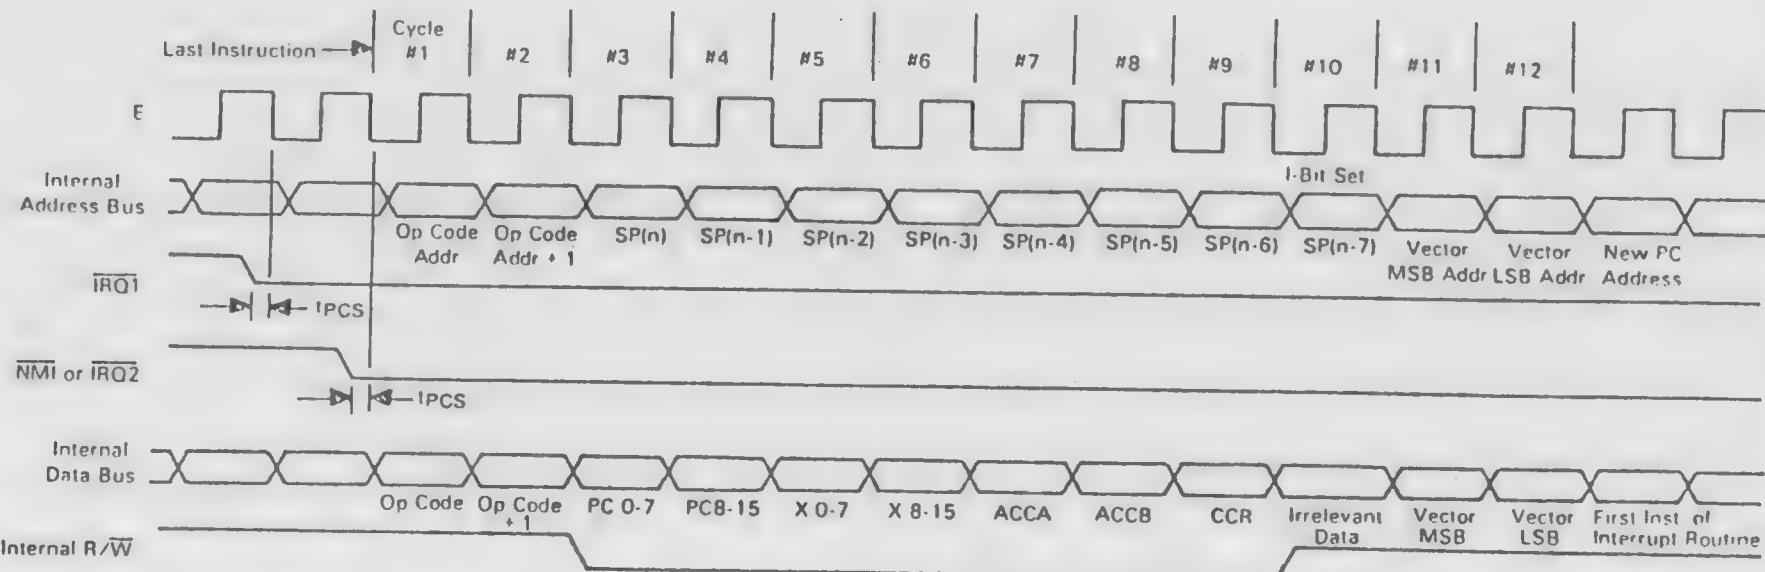

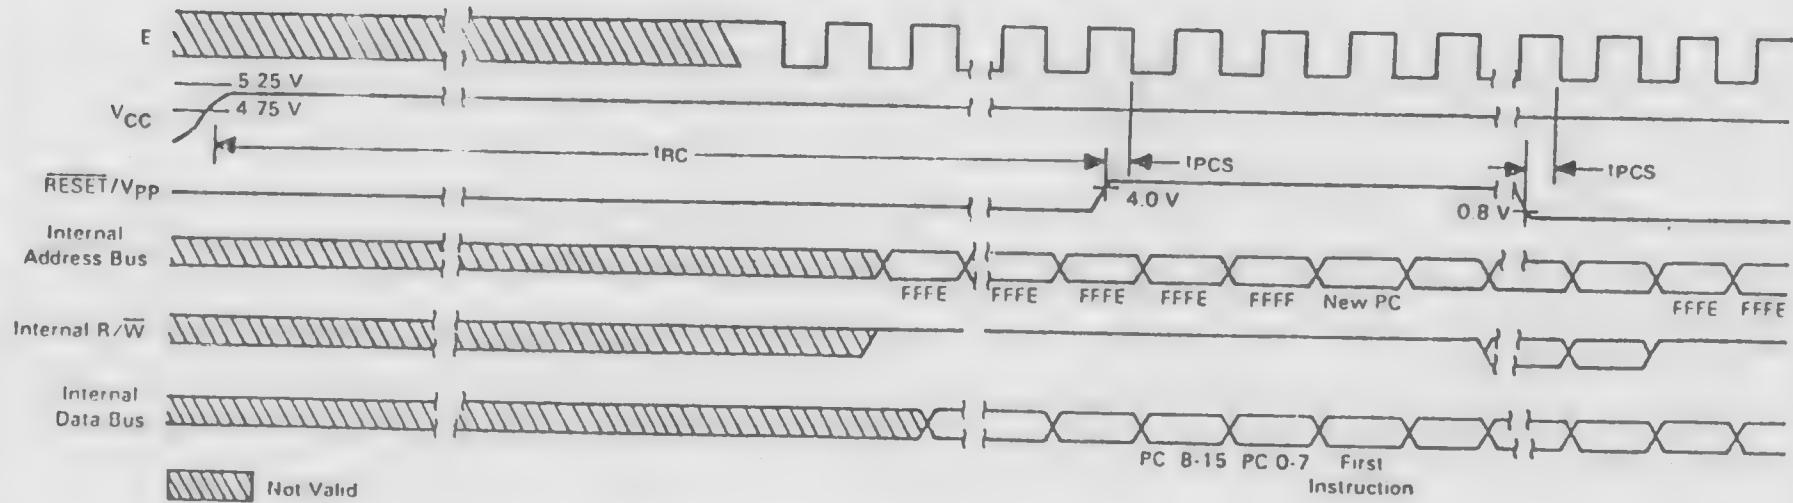

FIGURE 21b - RESET TIMING

fetched from \$FFF8 and \$FFF9 (or 1BFFF8 and 1BFFF9 in Mode 0), transferred to the Program Counter, and instruction execution is resumed.

IRQ1 typically requires an external  $3.3\text{ k}\Omega$  (nominal) resistor to  $V_{CC}$  for wire-OR applications. IRQ1 has no internal pullup resistor.

#### SC1 AND SC2 (STROBE CONTROL 1 AND 2)

The function of SC1 and SC2 depends on the operating mode. SC1 is configured as an output in all modes except single chip mode, whereas SC2 is always an output. SC1 and SC2 can drive one Schottky load and 90 pF.

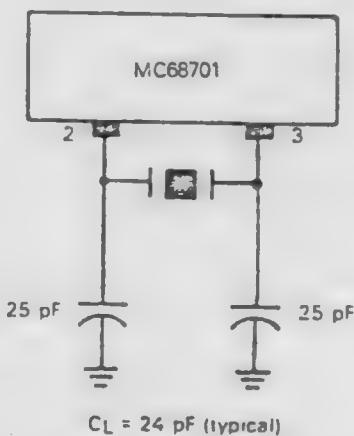

#### IN OUT SC1 and SC2 In Single Chip Mode

In Single Chip Mode, SC1 and SC2 are configured as an input and output, respectively, and both function as Port 3 control lines. SC1 functions as  $\overline{IS3}$  and can be used to indicate that Port 3 input data is ready or output data has been accepted. Three options associated with  $\overline{IS3}$  are controlled by the Port 3 Control and Status Register and are discussed in the Port 3 description. If unused,  $\overline{IS3}$  can remain unconnected.

SC2 is configured as  $\overline{OS3}$  and can be used to strobe output data or acknowledge input data. It is controlled by Output Strobe Select (OSS) in the Port 3 Control and Status Register. The strobe is generated by a read ( $OSS = 0$ ) or write ( $OSS = 1$ ) to the Port 3 Data Register.  $\overline{OS3}$  timing is shown in Figure 5. *page 3*

MOTOROLA Semiconductor Products Inc.

### SC1 And SC2 In Expanded Non-Multiplexed Mode

In the Expanded Non-Multiplexed Mode, both SC1 and SC2 are configured as outputs. SC1 functions as Input/Output Select (IOS) and is asserted only when \$0100 through \$01FF is sensed on the internal address bus.

SC2 is configured as Read/Write and is used to control the direction of data bus transfers. An MPU read is enabled when Read/Write and E are high.

### SC1 And SC2 In Expanded Multiplexed Mode

In the Expanded Multiplexed Modes, both SC1 and SC2 are configured as outputs. SC1 functions as Address Strobe and can be used to demultiplex the eight least significant addresses and the data bus. A latch controlled by Address Strobe captures address on the negative edge, as shown in Figure 16.

SC2 is configured as Read/Write and is used to control the direction of data bus transfers. An MPU read is enabled when Read/Write and E are high.

### P10-P17 (PORT 1)

Port 1 is a mode independent 8-bit I/O port where each line is an input or output as defined by its Data Direction Register. The TTL compatible three-state output buffers can drive one Schottky TTL load and 30 pF, Darlington transistors, or CMOS devices using external pullup resistors. It is configured as a data input port by RESET. Unused lines can remain unconnected.

### P20-P24 (PORT 2)

Port 2 is a mode independent 5-bit I/O port where each line is configured by its Data Direction Register. During RESET, all lines are configured as inputs. The TTL compatible three-state output buffers can drive one Schottky TTL load and 30 pF or CMOS devices using external pullup resistors. P20, P21, and P22 must always be connected to provide the operating mode. If lines P23 and P24 are unused, they can remain unconnected.

P20, P21, and P22 provide the operating mode which is latched into the Program Control Register on the positive edge of RESET. The mode may be read from the Port 2 Data Register as shown where PC2 is latched from pin 10.

Port 2 also provides an interface for the Serial Communications Interface and Timer. Bit 1, if configured as an output, is dedicated to the timer's Output Compare function and cannot be used to provide output from the Port 2 Data Register.

### POR T2 DATA REGISTER

7	6	5	4	3	2	1	0	
PC2	PC1	PC0	P24	P23	P22	P21	P20	\$0003

### P30-P37 (PORT 3)

Port 3 can be configured as an I/O port, a bidirectional 8-bit data bus, or a multiplexed address/data bus depending on the operating mode. The TTL compatible three-state output buffers can drive one Schottky TTL load and 90 pF. Unused lines can remain unconnected.

### Port 3 In Single-Chip Mode

Port 3 is an 8-bit I/O port in Single-Chip Mode where each line is configured by its Data Direction Register. There are also two lines, IS3 and OS3, which can be used to control Port 3 data transfers.

Three Port 3 options are controlled by the Port 3 Control and Status Register and available only in Single-Chip Mode: (1) Port 3 input data can be latched using IS3 as a control signal, (2) OS3 can be generated by either an MPU read or write to the Port 3 Data Register, and (3) an IRQ1 interrupt can be enabled by an IS3 negative edge. Port 3 latch timing is shown in Figure 6.

### POR T3 CONTROL AND STATUS REGISTER

7	6	5	4	3	2	1	0	
IS3 Flag	IS3 IRQ1 Enable	X	OS3	Latch Enable	X	X	X	\$000F

Bit 0-2

Bit 3

Bit 4

Bit 5

Bit 6

Bit 7

Not used.

LATCH ENABLE. This bit controls the input latch for Port 3. If set, input data is latched by an IS3 negative edge. The latch is transparent after a read of Port 3 Data Register. LATCH ENABLE is cleared by RESET.

OS3 (Output Strobe Select). This bit determines whether OS3 will be generated by a read or write of the Port 3 Data Register. When clear, the strobe is generated by a read; when set, it is generated by a write. OS3 is cleared by RESET.

Not used.

IS3 IRQ1 ENABLE. When set, an IRQ1 interrupt will be enabled whenever IS3 FLAG is set; when clear, the interrupt is inhibited. This bit is cleared by RESET.

IS3 FLAG. This read-only status bit is set by an IS3 negative edge. It is cleared by a read of the Port 3 Control and Status Register (with IS3 FLAG set) followed by a read or write to the Port 3 Data Register or by RESET.

### Port 3 In Expanded Non-Multiplexed Mode

Port 3 is configured as a bidirectional data bus (D7-D0) in the Expanded Non-Multiplexed Mode. The direction of data transfers is controlled by Read/Write (SC2) and clocked by E (Enable).

### Port 3 In Expanded Multiplexed Mode

Port 3 is configured as a time multiplexed address (A0-A7) and data bus (D7-D0) in Expanded Multiplexed Mode where Address Strobe (AS) can be used to demultiplex the two buses. Port 3 is held in a high impedance state between valid address and data to prevent potential bus conflicts.

**MOTOROLA** Semiconductor Products Inc.

#### P40-P47 (PORT 4)

Port 4 is configured as an 8-bit I/O port, as address outputs, or data inputs depending on the operating mode. Port 4 can drive one Schottky TTL load and 90 pF and is the only port with internal pullup resistors. Unused lines can remain unconnected.

#### Port 4 In Single Chip Mode

In Single Chip Mode, Port 4 functions as an 8-bit I/O port where each line is configured by the Data Direction Register. Internal pullup resistors allow the port to directly interface with CMOS at 5 volt levels. External pullup resistors to more than 5 volts, however, cannot be used.

#### Port 4 In Expanded Non-Multiplexed Mode

Port 4 is configured from RESET as an 8-bit input port where the Data Direction Register can be written to provide any or all of address lines A0 to A7. Internal pullup resistors are intended to pull the lines high until the Data Direction Register is configured.

#### Port 4 In Expanded Multiplexed Mode

In all Expanded Multiplexed modes except Mode 6, Port 4 functions as half of the address bus and provides A8 to A15. In Mode 6, the port is configured from RESET as an 8-bit parallel input port where the Data Direction Register can be written to provide any or all of address lines A8 to A15. Internal pullup resistors are intended to pull the lines high until its Data Direction Register is configured where bit 0 controls A8.

### RESIDENT MEMORY

The MC68701 has 128 bytes of onboard RAM and 2048 bytes of onboard UV erasable EPROM. This memory is controlled by four bits in the RAM/EPROM Control Register.

#### RAM/EPROM CONTROL REGISTER (\$14)

The RAM/EPROM Control Register includes four bits: STBY PWR, RAME, PPC, and PLC. Two of these bits, STBY PWR and RAME, are used to control RAM access and determine the adequacy of the standby power source during power-down operation. It is intended that RAME be cleared and STBY PWR be set as part of a power-down procedure. RAME and STBY PWR are Read/Write bits.

The remaining two bits, PLC and PPC, control the operation of the EPROM. PLC and PPC are readable in all modes but can be changed only in Mode 0. The PLC bit can be written without restriction in Mode 0, but operation of the PPC bit is controlled by the state of PLC.

Associated with the EPROM are an 8-bit data latch and a 16-bit address latch. The data latch is enabled at all times, latching each data byte written to the EPROM. The address latch is controlled by the PLC bit.

A description of the RAM/EPROM Control Register follows.

#### MC68701 RAM/EPROM CONTROL REGISTER

	7	6	5	4	3	2	1	0
STBY PWR	RAME	X	X	X	X	PPC	PLC	\$14

Bit 0

PLC. Programming Latch Control. This bit controls (a) a latch which captures the EPROM address to be programmed and (b) whether the PPC bit can be cleared. The latch is triggered by an MPU write to a location in the EPROM. This bit is set by Reset and can be cleared only in Mode 0. The PLC bit is defined as follows:

PLC=0 EPROM address latch enabled; EPROM address is latched during MPU writes to the EPROM.

PLC=1 EPROM address latch is transparent.

PPC. Programming Power Control. This bit gates power from the RESET/Vpp pin to the EPROM programming circuit. PPC is set by Reset and whenever the PLC bit is set. It can be cleared only if (a) operating in Mode 0, and (b) if PLC has been previously cleared. The PPC bit is defined as follows:

PPC=0 EPROM programming power (Vpp) enabled.

PPC=1 EPROM programming power (Vpp) is not applied.

Unused.

RAME. RAM Enable. This Read/Write bit can be used to remove the entire RAM from the internal memory map. RAME is set (enabled) during Reset provided standby power is available on the positive edge of RESET. If RAME is clear, any access to a RAM address is external. If RAME is set and not in Mode 3, the RAM is included in the internal map.

Bit 7 STBY PWR

Standby Power. This bit is a Read/Write status bit which is cleared whenever VCC Standby decreases below VSBB (min). It can be set only by software and is not affected by RESET.

Note that if PPC and PLC are set, they cannot be simultaneously cleared as the result of a single MPU write. The PLC bit must be cleared prior to attempting to clear PPC. If both PPC and PLC are clear, setting PLC will also set PPC. In addition, it is assumed that Vpp is applied to the RESET/Vpp pin whenever PPC is clear. If this is not the case, the result is undefined.

#### ERASING THE MC68701 EPROM

Ultraviolet erasure will clear all bits of the EPROM to the "0" state. Note that this erased state differs from that of some other widely used EPROMs (such as the MCM68702) where the erased state is a "1". The MC68701 EPROM is programmed by erasing it to "0's" and entering "1's" into the desired bit locations.

MOTOROLA Semiconductor Products Inc.

The MC68701 EPROM can be erased by exposure to high intensity ultraviolet light with a wave length of 2537 Å. The recommended integrated dose (UV intensity X exposure time) is 15 Ws/cm<sup>2</sup>. The lamps should be used without shortwave filters and the MC68701 should be positioned about one inch away from the UV tubes.

The MC68701 transparent lid should always be covered after erasing. This protects both the EPROM and light-sensitive nodes from accidental exposure to ultraviolet light.

### PROGRAMMING THE MC68701 EPROM

When the MC68701 is released from Reset in Mode 0, a vector is fetched from location \$BFFE:FFFF. This provides a method for an external program to obtain control of the microcomputer with access to every location in the EPROM.

To program the EPROM, it is necessary to operate the MC68701 in Mode 0 under the control of a program resident in external memory which can facilitate loading and programming of the EPROM. After the pattern has been loaded into external memory, the EPROM can be programmed as follows:

- a. Apply programming power (Vpp) to the RESET/VPP pin.
- b. Clear the PLC control bit and set the PPC bit by writing \$FE to the RAM/EPROM Control Register.
- c. Write data to the next EPROM location to be programmed. Triggered by an MPU write to the EPROM, internal latches capture both the EPROM address and the data byte.
- d. Clear the PPC bit for programming time, tpp, by writing \$FC to the RAM/EPROM Control Register and waiting for time, tpp. This step gates the programming power (Vpp) from the RESET/VPP pin to the EPROM which programs the location.
- e. Repeat steps b through d for each byte to be programmed.
- f. Remove the programming power (Vpp) from the RESET/VPP pin. The EPROM can now be read and verified.

Because of the erased state of an EPROM byte is \$00, it is not necessary to program a location which is to contain \$00. Finally, it should be noted that the result of inadvertently programming a location more than once is the logical OR of the data patterns.

A routine which can be used to program the MC68701 EPROM is provided at the end of this data sheet. This non-reentrant routine requires four double byte variables named IMBEQ, IMEND, PNTR, and WAIT to be initialized prior to entry to the routine. These variables indicate (a) the first and last memory locations which bound the data to be programmed into the EPROM, (b) the first EPROM location to be programmed, and (c) a quantity which can be used to generate the programming time delay. The last variable, WAIT, takes into account the MCU input crystal (or TTL-compatible clock) frequency to insure the programming time, tpp, is met. WAIT is defined as the number of MPU E-cycles that will occur in the real-time EPROM programming interval, tpp. For example, if tpp = 50 milliseconds and the MC68701 is being driven with a 4.00 MHz TTL-compatible clock:

$$\begin{aligned} \text{WAIT (MPU E-cycles)} &= . \text{tpp} \cdot (\text{MCU INPUT FREQ})/4 \cdot 10^6 \\ &= 5000 \cdot (4 \cdot 10^6)/4 \cdot 10^6 \\ &= 5000 \end{aligned}$$

### PROGRAMMABLE TIMER

The Programmable Timer can be used to perform input waveform measurements while independently generating an output waveform. Pulse widths can vary from several microseconds to many seconds. A block diagram of the Timer is shown in Figure 23.

#### COUNTER (\$09:0A)

The key timer element is a 16-bit free-running counter which is incremented by E (Enable). It is cleared during RESET and is read-only with one exception: a write to the counter (\$09) will preset it to \$FFF8. This feature, intended for testing, can disturb serial operations because the counter provides the SCI's internal bit rate clock. TOF is set whenever the counter contains all 1's.

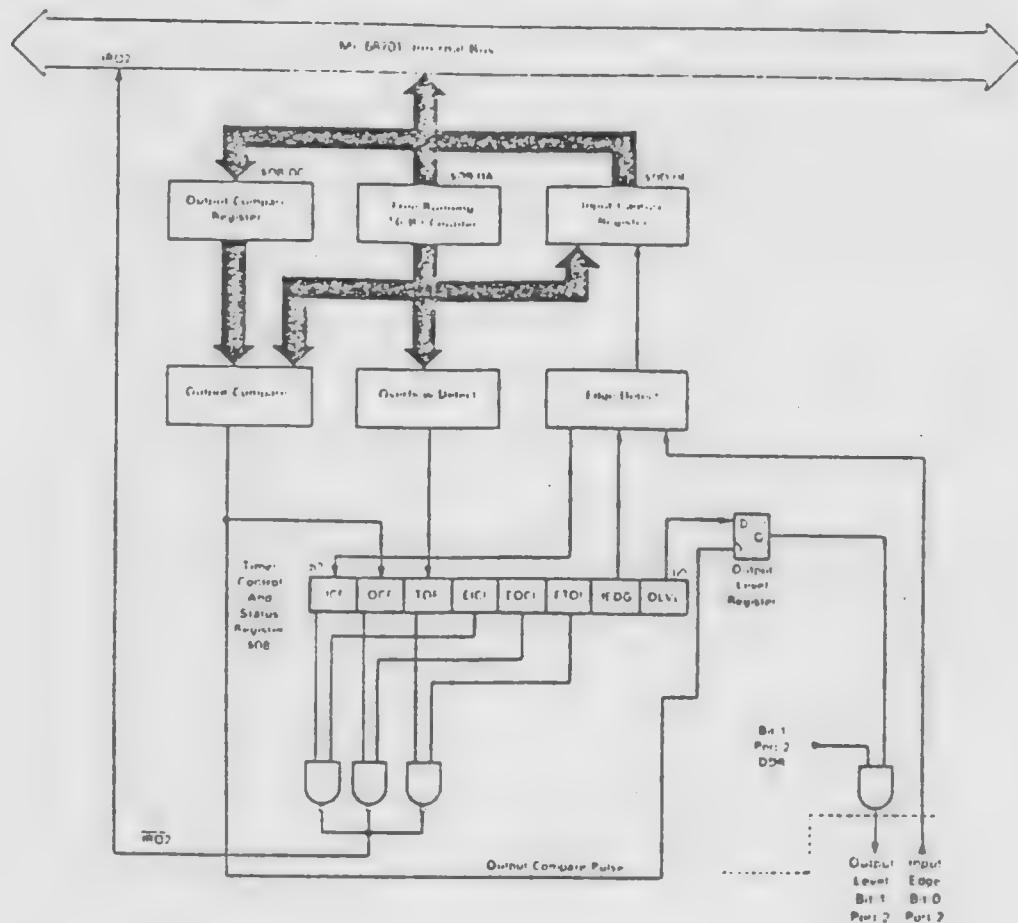

#### OUTPUT COMPARE REGISTER (\$0B:0C)

The Output Compare Register is a 16-bit Read/Write register used to control an output waveform or provide an arbitrary timeout flag. It is compared with the free-running counter on each E-cycle. When a match is found, OCF is set and OLVL is clocked to an output level register. If Port 2, bit 1, is configured as an output, OLVL will appear at P21 and the Output Compare Register and OLVL can then be

**MOTOROLA Semiconductor Products Inc.**

FIGURE 23 – BLOCK DIAGRAM OF PROGRAMMABLE TIMER

changed for the next compare. The function is inhibited for one cycle after a write to the high byte of the Compare Register (\$0B) to ensure a valid compare. The Output Compare Register is set to \$FFFF by RESET.

#### INPUT CAPTURE REGISTER (\$0D:0E)

The Input Capture Register is a 16-bit read-only register used to store the free-running counter when a "proper" input transition occurs as defined by IEDG. Port 2, bit 0 should be configured as an input, but the edge detect circuit always senses P20 even when configured as an output. An input capture can occur independently of ICF: the register always contains the most current value. Counter transfer is inhibited, however, between accesses of a double byte MPU read. The input pulse width must be at least two E-cycles to ensure an input capture under all conditions.

#### TIMER CONTROL AND STATUS REGISTER (\$08)

The Timer Control and Status Register (TCSR) is an 8-bit register of which all bits are readable while bits 0-4 can be written. The three most significant bits provide the timer's status and indicate if:

- a proper level transition has been detected,
- a match has been found between the free-running counter and the output compare register, and
- the free-running counter has overflowed.

Each of the three events can generate an IRQ2 interrupt and is controlled by an individual enable bit in the TCSR.

#### TIMER CONTROL AND STATUS REGISTER (TCSR)

7	6	5	4	3	2	1	0
ICF	OCF	TOF	EICI	EOCI	ETOI	IEDG	OLVL

\$0008

##### Bit 0 OLVL

Output level. OLVL is clocked to the output level register by a successful output compare and will appear at P21 if Bit 1 of Port 2's Data Direction Register is set. It is cleared by RESET. Input Edge. IEDG is cleared by RESET and controls which level transition will trigger a counter transfer to the Input Capture Register:

- IEDG=0 Transfer on a negative-edge
- IEDG=1 Transfer on a positive-edge

Enable Timer Overflow Interrupt. When set, an IRQ2 interrupt is enabled for a timer overflow; when clear, the interrupt is inhibited. It is cleared by RESET.

**MOTOROLA Semiconductor Products Inc.**

Bit 3 EOC1	Enable Output Compare Interrupt. When set, an <u>IRQ2</u> interrupt is enabled for an output compare; when clear, the interrupt is inhibited. It is cleared by <u>RESET</u> .
Bit 4 EICI	Enable Input Capture Interrupt. When set, an <u>IRQ2</u> interrupt is enabled for an input capture; when clear, the interrupt is inhibited. It is cleared by <u>RESET</u> .
Bit 5 TOF	Timer Overflow Flag. TOF is set when the counter contains all 1's. It is cleared by reading the TCSR (with TOF set) followed by the counter's high byte (\$09), or by <u>RESET</u> .
Bit 6 OCF	Output Compare Flag. OCF is set when the Output Compare Register matches the free-running counter. It is cleared by reading the TCSR (with OCF set) and then writing to the Output Compare Register (\$0B or \$0C), or by <u>RESET</u> .
Bit 7 ICF	Input Capture Flag. ICF is set to indicate a proper level transition; it is cleared by reading the TCSR (with ICF set) and then the Input Capture Register High Byte (\$0D), or by <u>RESET</u> .

### SERIAL COMMUNICATIONS INTERFACE (SCI)

A full-duplex asynchronous Serial Communications Interface (SCI) is provided with two data formats and a variety of rates. The SCI transmitter and receiver are functionally independent, but use the same data format and bit rate. Serial data formats include standard mark/space (NRZ) and Bi-phase and both provide one start bit, eight data bits, and one stop bit. "Baud" and "bit rate" are used synonymously in the following description.

### WAKE-UP FEATURE

In a typical serial loop multi-processor configuration, the software protocol will usually identify the addressee(s) at the beginning of the message. In order to permit uninterested MPU's to ignore the remainder of the message, a wake-up feature is included whereby all further SCI receiver flag (and interrupt) processing can be inhibited until the data line goes idle. An SCI receiver is re-enabled by an idle string of ten consecutive 1's or by RESET. Software must provide for the required idle string between consecutive messages and prevent it within messages.

### PROGRAMMABLE OPTIONS

The following features of the SCI are programmable:

- format: standard mark/space (NRZ) or Bi-phase
- clock: external or internal bit rate clock
- Baud (or bit rate): one of 4 per E-clock frequency, or external bit rate (X&I) input
- wake-up feature: enabled or disabled
- interrupt requests: enabled individually for transmitter and receiver
- clock output: internal bit rate clock enabled or disabled to P22

### SERIAL COMMUNICATIONS REGISTERS

The Serial Communications Interface includes four addressable registers as depicted in Figure 24. It is controlled by the Rate and Mode Control Register and the Transmit/Receive Control and Status Register. Data is transmitted and received utilizing a write-only Transmit Register and a read-only Receive Register. The shift registers are not accessible to software.

#### Rate and Mode Control Register (RMCR) (\$10)

The Rate and Mode Control Register controls the SCI bit rate, format, clock source, and under certain conditions, the configuration of P22. The register consists of four write-only bits which are cleared by RESET. The two least significant bits control the bit rate of the internal clock and the remaining two bits control the format and clock source.

#### RATE AND MODE CONTROL REGISTER (RMCR)

7	6	5	4	3	2	1	0
X	X	X	X	CC1	CC0	SS1	SS0

Bit 1:Bit 0

SS1:SS0 Speed Select. These two bits select the Baud when using the internal clock. Four rates may be selected which are a function of the MCU input frequency. Table 6 lists bit time and rates for three selected MCU frequencies.

Bit 3:Bit 2

CC1:CC0 Clock Control and Format Select. These two bits control the format and select the serial clock source. If CC1 is set, the DDR value for P22 is forced to the complement of CC0 and cannot be altered until CC1 is cleared. If CC1 is cleared after having been set, its DDR value is unchanged. Table 7 defines the formats, clock source, and use of P22.

If both CC1 and CC0 are set, an external TTL compatible clock must be connected to P22 at eight times (8X) the desired bit rate, but not greater than E, with a duty cycle of 50% ( $\pm 10\%$ ). If CC1:CC0 = 10, the internal bit rate clock is provided at P22 regardless of the values for TE or RE.

**NOTE:** The source of SCI internal bit rate clock is the timer's free running counter. An MPU write to the counter can disturb serial operations.

#### Transmit/Receive Control And Status Register (TRCSR) (\$11)

The Transmit/Receive Control and Status Register controls the transmitter, receiver, wake-up feature, and two individual interrupts and monitors the status of serial operations. All eight bits are readable while bits 0 to 4 are also writable. The register is initialized to \$20 by RESET.

#### TRANSMIT/RECEIVE CONTROL AND STATUS REGISTER (TRCSR)

FIGURE 24 — SCI REGISTERS

MOTOROLA Semiconductor Products Inc.

Bit 0 WU	"Wake-up" on Idle Line. When set, WU enables the wake-up function; it is cleared by ten consecutive 1's or by RESET. WU will not set if the line is idle.	error has occurred when the byte boundaries of the bit stream are not synchronized to the bit counter. An overrun can be distinguished from a framing error by the value of RDRF: if RDRF is set, then an overrun has occurred; otherwise a framing error has been detected. Data is not transferred to the Receive Data Register in an overrun condition. ORFE is cleared by reading the TRCSR (with ORFE set) then the Receive Data Register, or by RESET.
Bit 1 TE	Transmit Enable. When set, P24 DDR bit is set, cannot be changed, and will remain set if TE is subsequently cleared. When TE is changed from clear to set, the transmitter is connected to P24 and a preamble of nine consecutive 1's is transmitted. TE is cleared by RESET.	Bit 7 RDRF
Bit 2 TIE	Transmit Interrupt Enable. When set, an IRQ2 interrupt is enabled when TDRE is set; when clear, the interrupt is inhibited. TE is cleared by RESET.	Receive Data Register Full. RDRF is set when the input serial shift register is transferred to the Receive Data Register. It is cleared by reading the TRCSR (with RDRF set), and then the Receive Data Register, or by RESET.
Bit 3 RE	Receive Enable. When set, the P23 DDR bit is cleared, cannot be changed, and will remain clear if RE is subsequently cleared. While RE is set, the SCI receiver is enabled. RE is cleared by RESET.	
Bit 4 RIE	Receiver Interrupt Enable. When set, an IRQ2 interrupt is enabled when RDRF and/or ORFE is set; when clear, the interrupt is inhibited. RIE is cleared by RESET.	
Bit 5 TDRE	Transmit Data Register Empty. TDRE is set when the Transmit Data Register is transferred to the output serial shift register or by RESET. It is cleared by reading the TRCSR (with TDRE set) and then writing to the Transmit Data Register. Additional data will be transmitted only if TDRE has been cleared.	
Bit 6 ORFE	Overrun Framing Error. If set, ORFE indicates either an overrun or framing error. An overrun is a new byte ready to transfer to the Receive Data Register with RDRF still set. A receiver framing	

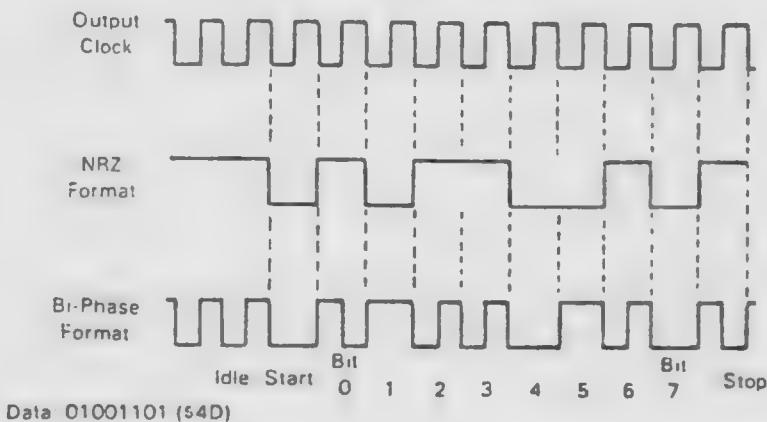

## SERIAL OPERATIONS

The SCI is initialized by writing control bytes first to the Rate and Mode Control Register and then, to the Transmit/Receive Control and Status Register. When TE is set, the output of the transmit serial shift register is connected to P24 and serial output is initiated by transmitting to 9-bit preamble of 1's.

At this point one of two situations exist: 1) if the Transmit Data Register is empty (TDRE = 1), a continuous string of 1's will be sent indicating an idle line, or 2) if a byte has been written to the Transmit-Data Register (TDRE = 0), it will be transferred to the output serial shift register (synchronized with the bit rate clock), TDRE will be set, and transmission will begin.

The start bit (0), eight data bits (beginning with bit 0) and a stop bit (1), will be transmitted. If TDRE is still set when the next byte transfer should occur, 1's will be sent until more data is provided. In Bi-phase format, the output toggles at the start of each bit and at half-bit time when a "1" is sent. Receive operation is controlled by RE which configures P23 as an input and enables the receiver. SCI data formats are illustrated in Figure 25.

## INSTRUCTION SET

The MC68701 is upward source and object code compatible with the MC6800. Execution times of key instructions have been reduced and several new instructions have been added, including a hardware multiply. A list of new operations added to the MC6800 instruction set is shown in Table 1.

In addition, two new special opcodes, 4E and 5E, are provided for test purposes. These opcodes force the Program Counter to increment like a 16-bit counter, causing address lines used in the expanded modes to increment until the device is reset. These opcodes have no mnemonics.

## PROGRAMMING MODEL

A programming model for the MC68701 is shown in Figure 11. Accumulator A can be concatenated with accumulator B and jointly referred to as accumulator D where A is the most significant byte. Any operation which modifies the double accumulator will also modify accumulator A and/or B. Other registers are defined as follows:

**Program Counter** — The program counter is a 16-bit register which always points to the next instruction.

**Stack Pointer** — The stack pointer is a 16-bit register which contains the address of the next available location in a pushdown/pullup (LIFO) queue. The stack resides in random access memory at a location defined by the programmer.

**Index Register** — The Index Register is a 16-bit register which can be used to store data or provide an address for the indexed mode of addressing.

**Accumulators** — The MCU contains two 8-bit accumulators, A and B, which are used to store operands and results from the arithmetic logic unit (ALU). They can also be concatenated and referred to as the D (double) accumulator.

**Condition Code Registers** — The condition code register indicates the results of an instruction and includes the following five condition bits: Negative (N), Zero (Z), Overflow (V), Carry/Borrow from MSB (C), and Half Carry from bit 3 (H). These bits are testable by the conditional branch instructions. Bit 4 is the interrupt mask (1-bit) and inhibits all maskable interrupts when set. The two unused bits, b6 and b7 are read as ones.

## ADDRESSING MODES

The MC68701 provides six addressing modes which can be used to reference memory. A summary of addressing modes for all instructions is presented in Tables 8, 9, 10, and 11 where execution times are provided in E-cycles. Instruction execution times are summarized in Table 12. With an input frequency of 4 MHz, E-cycles are equivalent to microseconds. A cycle-by-cycle description of bus activity for each instruction is provided in Table 13 and a description of selected instructions is shown in Figure 26.

**Immediate Addressing** — The operand or "immediate byte(s)" is contained in the following byte(s) of the instruction where the number of bytes matches the size of the register. These are two or three byte instructions.

**Direct Addressing** — The least significant byte of the operand address is contained in the second byte of the instruction and the most significant byte is assumed to be \$00. Direct addressing allows the user to access \$00 through \$FF using two byte instructions and execution time is reduced by eliminating the additional memory access. In most applications, the 256-byte area is reserved for frequently referenced data.

**Extended Addressing** — The second and third bytes of the instruction contain the absolute address of the operand. These are three byte instructions.

**Indexed Addressing** — The unsigned offset contained in the second byte of the instruction is added with carry to the Index Register and used to reference memory without changing the Index Register. These are two byte instructions.

**Inherent Addressing** — The operand(s) are registers and no memory reference is required. These are single byte instructions.

**Relative Addressing** — Relative addressing is used only for branch instructions. If the branch condition is true, the Program Counter is overwritten with the sum of a signed single byte displacement in the second byte of the instruction and the current Program Counter. This provides a branch range of -126 to 129 bytes from the first byte of the instruction. These are two byte instructions.

## SUMMARY OF CYCLE BY CYCLE OPERATION

Table 13 provides a detailed description of the information present on the Address Bus, Data Bus, and the Read/Write (R/W) line during each cycle of each instruction.

The information is useful in comparing actual with expected results during debug of both software and hardware as the program is executed. The information is categorized in groups according to addressing mode and number of cycles

per instruction. In general, instructions with the same addressing mode and number of cycles execute in the same manner. Exceptions are indicated in the table.

Note that during MPU reads of internal locations, the resultant value will not appear on the external Data Bus except in Mode 0. "High order" byte refers to the most significant byte of a 16-bit value.

TABLE 13 — CYCLE BY CYCLE OPERATION

Address Mode & Instructions	Cycles	Cycle #	Address Bus	R/W Line	Data Bus
